

# 9th Standard-Maths

## Constructions

1. **Need of Accurate Figures:** Sometimes one needs an accurate figure, for example, to draw a map of a building to be constructed, to design tools and various parts of a machine, to draw road maps, etc. To draw such figures some basic geometrical instruments are needed.

2. **Geometry Box:** A geometry box contains the following basic geometrical instruments

- A graduated scale, on one side of which centimetres and Millimetres are marked off and on the other side inches and their parts is marked off.
- A pair of set squares, one with angles  $90^\circ$ ,  $60^\circ$  and  $30^\circ$  and other with angles  $90^\circ$ ,  $45^\circ$  and  $45^\circ$ .
- A pair of dividers (or a divider) with adjustments.
- A pair of compasses (or a compass) with the provision of fitting a pencil at one end.
- A protractor.

Normally, all these instruments are needed in drawing a geometrical figure such as a triangle, a circle, a quadrilateral a polygon etc. with given measurements but a geometrical construction is the process of drawing a geometrical figure using only two instruments—an ungraduated ruler, also called a straight edge and  $\alpha$ -compass. In construction, where measurements are also required, we may use a graduated scale and protractor also.

### 3. Basic Constructions

#### (I) To construct the bisector of a given angle

**Given:** An  $\angle ABC$ .

**Required:** To construct its bisector.

#### Steps of Construction:

- (i) Taking B as centre and any radius, draw an arc to intersect the rays BA and BC, say at E and D, respectively.
- (ii) Next, taking D and E as centres and with the radius more than  $\frac{1}{2} DE$ , draw arcs to intersect each other, say at F.
- (iii) Draw the ray BF. This ray BF is the required bisector of the  $\angle ABC$ .

**Proof:** Join DF and EF.

In  $\triangle BEF$  and  $\triangle BDF$ ,

$BE = BD$  (Radii of the same arc)

$EF = DF$  (Arcs of radii)

$BF = BF$  (Common)

Therefore,  $\triangle BEF = \triangle BDF$  (SSS rule)

This gives  $\angle EBF = \angle DBF$  (CPCT)

#### (II) To construct the perpendicular bisector of a given line segment

**Given:** A line segment AB.

**Required:** To construct its perpendicular bisector.

### Steps of Construction:

- (i) Taking A and B as centres and radius more than  $\frac{1}{2}$  AB, draw arcs on both sides of the line segment AB (to intersect each other).
- (ii) Let these arcs intersect each other at P and Q. Join PQ.
- (iii) Let PQ intersect AB at the point M. Then, line PMQ is the required perpendicular bisector of AB.

**Proof:** Join A and B to both P and Q to form AP, AQ, BP and BQ.

In  $\triangle PAQ$  and  $\triangle PBQ$ ,

$AP = BP$  (Arcs of equal radii)

$AQ = BQ$  (Arcs of equal radii)

$PQ = PQ$  (Common)

Therefore,  $\triangle PAQ = \triangle PBQ$  (SSS rule)

So,  $\angle APM = \angle BPM$  (CPCT)

Now, in  $\triangle PMA$  and  $\triangle PMB$ ,

$AP = BP$  (As before)

$PM = PM$  (Common)

$\angle APM = \angle BPM$  (Proved above)

Therefore,  $\triangle PMA = \triangle PMB$  (SAS rule)

So,  $AM = BM$  and  $\angle PMA = \angle PMB$

As  $\angle PMA + \angle PMB = 180^\circ$  (Linear pair axiom)

We get,  $\angle PMA = \angle PMB = 90^\circ$

Therefore, PM, i.e., PMQ is the perpendicular bisector of AB.

**(III) Constructs an angle of  $60^\circ$  at the initial point of a given ray**

**Given:** A ray AB with initial point A.

**Required:** To construct a ray AC such that  $\angle CAB = 60^\circ$ .

**Steps of Construction:**

- (i) Taking A as the centre and some radius, draw an arc of a circle which intersects AB, say at a point D.
- (ii) Taking D as the centre and with the same radius as before, draw an arc intersecting the previously drawn arc, say at a point E.
- (iii) Draw the ray AC passing through E. Then  $\angle CAB$  required the angle of  $60^\circ$ .

**Proof:** Join DE.

Then,  $AD = DE$  (By construction)

Therefore,  $\triangle ADE$  is an equilateral triangle and the  $\angle EAD$  which is the same as  $\angle CAB$  is equal to  $60^\circ$ .

4. Rules of Congruency of Two Triangles

- SAS Two triangles are congruent if any two sides and the included angle of one triangle are equal to any two sides and the included angle of the other triangle.
- SSS Two triangles are congruent if the three sides of one triangle are equal to the three sides of the other triangle.
- ASA Two triangles are congruent if any two angles and the included side of one triangle are equal to the two angles and the included side of the other triangle.
- RHS Two right triangles are congruent if the hypotenuse and a side of one triangle are respectively equal to the hypotenuse and a side of the other triangle.

#### 5. The uniqueness of a Triangle

A triangle is unique, if

- two sides and the included angle is given,
- three sides are given,
- two angles and the included side is given and
- in a right triangle, hypotenuse and one side are given.

**6. Requirement for the Construction of a Triangle:** For constructing a triangle, at least three parts of a triangle have to be given but, not all combinations of three parts are sufficient for the purpose, e.g., if two sides and an angle (not the included angle) are given, then it is not always possible to construct such a triangle uniquely.

7. Some Constructions of Triangles

**(I) To construct a triangle, given its base, a base angle and sum of other two sides**

**Given:** The base BC, a base angle, say  $\angle B$  and the sum  $AB + AC$  of the other two sides of a  $\triangle ABC$ .

**Required:** To construct the  $\triangle ABC$ .

**Steps of Construction:**

- (i) Draw the base BC and at the point B make an angle, say XBC equal to the given angle.
- (ii) Cut a line segment BD equal to  $AB + AC$  from the ray BX.
- (iii) Join DC and make an angle DCY equal to  $\angle BDC$ .
- (iv) Let CY intersect BX at A (see figure).

**Justification**

Base BC and CB are drawn as given.

Next in  $\triangle ACD$ ,

$$\angle ACD = \angle ADC \text{ (By construction)}$$

$$AC = AD \text{ (Sides opposite to equal angles of a triangle are equal)}$$

$$AB = BD - AD = BD - AC$$

$$\Rightarrow AB + AC = BD$$

### Alternative Method

(i) Draw the base BC and at the point B make an angle, say XBC equal to the given angle.

(ii) Cut a line segment BD equal to AP + AC from the ray BX.

(iii) Join DC.

(iv) Draw perpendicular bisector PQ of CD to intersect BD at a point A.

(v) Join AC.

Then, ABC is the required triangle.

### Justification

Base BC and CB are drawn as given.

A lies on the perpendicular bisector of CD.

$$AD = AC$$

$$AB = BD - AD = BD - AC$$

$$AB + AC = BD$$

Remark: The construction of the triangle is not possible if the sum  $AB + AC < BC$ .

### (II) To construct a triangle given its base, a base angle and the difference of the other two sides

**Given:** The base BC, a base angle, say CB and the difference of other two sides

$AB - AC$  or  $AC - AB$ .

Required: To construct the  $\triangle ABC$ .

There are the following two cases

**Case (I):** Let  $AB > AC$ , i.e.,  $AB - AC$  is given.

**Steps of Construction:**

- (i) Draw the base  $BC$  and at point  $B$  make an angle, say  $\angle XBC$  equal to the given angle.
- (ii) Cut the line segment  $BD$  equal to  $AB - AC$  from ray  $BX$ .
- (iii) Join  $DC$  and draw the perpendicular bisector, say  $PQ$  of  $DC$ .
- (iv) Let it intersect  $BX$  at a point  $A$ . Join  $AC$ .

Then,  $ABC$  is the required triangle.

**Justification**

Base  $BC$  and  $\angle B$  are drawn as given.

The point  $A$  lies on the perpendicular bisector of  $DC$ .

$$AD = AC$$

$$\text{So, } BD = AB - AD = AB - AC$$

**Case (II):** Let  $AB < AC$  i.e.,  $AC - AB$  is given.

**Steps of Construction:**

- (i) Draw the base BC and at point B make an angle, say  $\angle XBC$  equal to the given angle.
  - (ii) Cut line segment BD equal to  $AC - AB$  from the line BX extended on an opposite side of line segment BC.
  - (iii) Join DC and draw the perpendicular bisector, say PQ of DC.
  - (iv) Let PQ intersect BX at A. Join AC.
- Then, ABC is the required triangle.

**Justification**

Base BC and CB are drawn as given.

The point A lies on the perpendicular bisector of DC.

$$AD = AC$$

$$\text{So, } BD = AD - AB = AC - AB$$

**(III) To construct a triangle, given its perimeter and its two base angles**

**Given:** The base angles, say  $\angle B$  and  $\angle C$  and  $BC + CA + AB$ .

**Required:** To construct the  $\Delta ABC$ .

Steps of Construction:

- (i) Draw a line segment, say XY equal to  $BC + CA + AB$ .
- (ii) Make angles LXY equal to  $\angle B$  and MYX equal to  $\angle C$ .
- (iii) Bisect  $\angle LXY$  and  $\angle MYX$ . Let these bisectors intersect a point A.

- (iv) Draw perpendicular bisectors PQ of AX and RS of AY.
- (v) Let PQ intersect XY at B and RS intersect XY at C. Join AB and AC.

Then, ABC is the required triangle.

### Justification

B lies on the perpendicular bisector PQ of AX.

$$\therefore XB = AB$$

C lies on the perpendicular bisector RS of AY.

$$\therefore CY = AC$$

This gives

$$BC + CA + AB = BC + XB + CY = XY$$

Again,  $\angle BAX + \angle AXB$  (in  $\triangle AXB$ ,  $AB = XB$ )

and  $\angle ABC = \angle BAX + \angle AXB = 2\angle AXB = \angle LXY$

Next,  $\angle CAY = \angle AYC$  (in  $\triangle AYC$ ,  $AC = CY$ )

and  $\angle ACB = \angle CAY + \angle AYC = 2\angle AYC = \angle MYX$

Thus, we have what is required.
